

Loads on columns calculations :-

- which
- 1 - Method of calculation of area applied on column.
 - 2 - Method of calculation of reaction from Beams to Columns. (Complicated method)

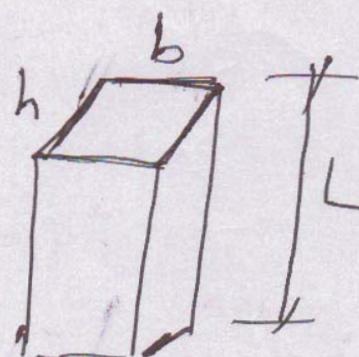

Columns specifications :-

Columns are compressive structural elements, which the height is greater than five times the smallest dimension of cross sectional area.

if $L > 5 * b$ (column)

~~(Structural stability)~~

* Short columns & Slender columns :- 4

$$\lambda_b = \frac{H_e}{b}, \quad \lambda_i = \frac{H_e}{i}$$

Check the following:-

$i = 0.3b$ (rectangular section)

$i = 0.25D$ (circular section)

H_e = Effective height of column.

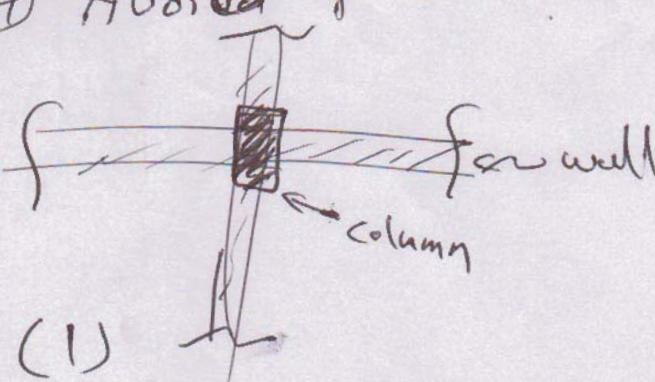

b = width of column cross-section.

D = Diameter of circular column.

<u>Case of column</u>	λ_b	λ_i
Braced	15	50
unbraced	10	35

* Columns Placing in drawings:-

- ① Put in intersection of walls
- ② Beginning with repeated floors.
- ③ Notice orientation of columns.
- ④ Avoided of cantilever columns.

Notes on Columns :-

- 1- Minimum longitudinal reinforcement ratio is 1%.
- 2- Maximum longitudinal reinforcement ratio 6%.
- 3- The column should be contained on bar in each corner.
- 4- Minimum bar diameter 12 mm as longitudinal reinforcement -
- 5- Minimum dimension of cross-sectional area of rectangular column is (200 mm) -
- 6- Maximum distance between longitudinal bars at corners (30 cm). If the distance greater than 30 cm intermediate bars shall be put with distances not more than 25 cm -
- 7- The column of circular cross-sectional area min. steel bars ~~number~~ number 15 (6).
- 8- The ~~distance~~ ^{spacing} between longitudinal bars shall be not more than 15 cm without ties; if more than 15 cm, ~~tie~~ ties shall be used -
- 9- The distance between ties should be not more than the following :-

a - Fifteen times the smallest bar diameter of longitudinal bars ⁷

b - Minimum dimension of column, but not more than 20 cm.

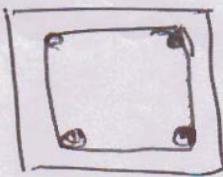

10 - Minimum diameter of tied bars is one fourth of maximum bar diameter of longitudinal bars, but not less than 8 mm.

11 - The ties shall be continue to beams connected with columns.

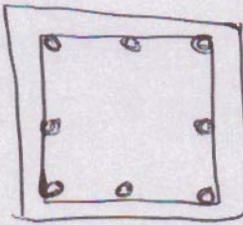

12 - For spiral column the spacing between 3-8 cm.

13 - The development length for lap splices of columns shall be not less than 40ϕ .

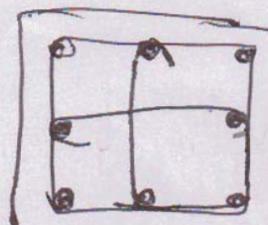

14 - The column has ~~smallest thickness~~ $h < s_b$, if $h > s_b$ considered RC wall.

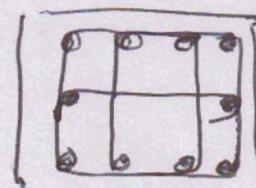

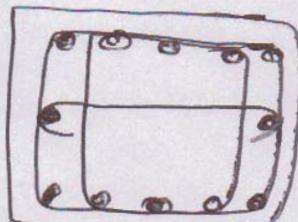

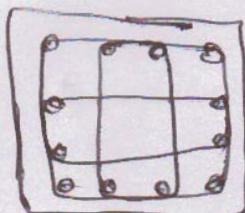

Spacing $\leq 30\text{cm}$

Spacing $\leq 15\text{cm}$

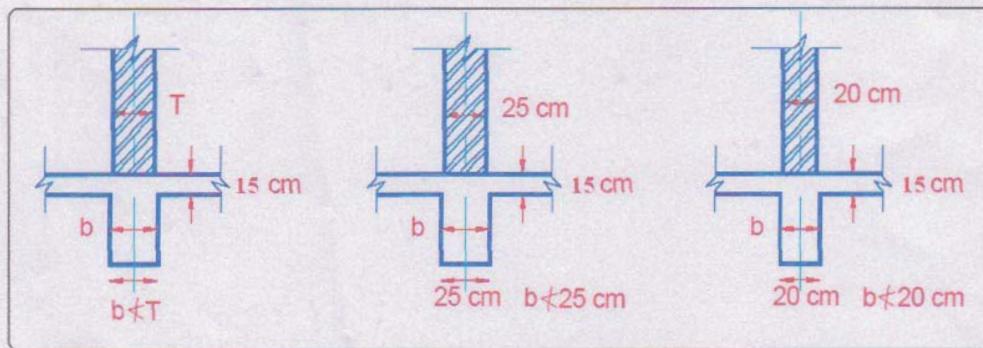

Spacing $> 15\text{cm}$

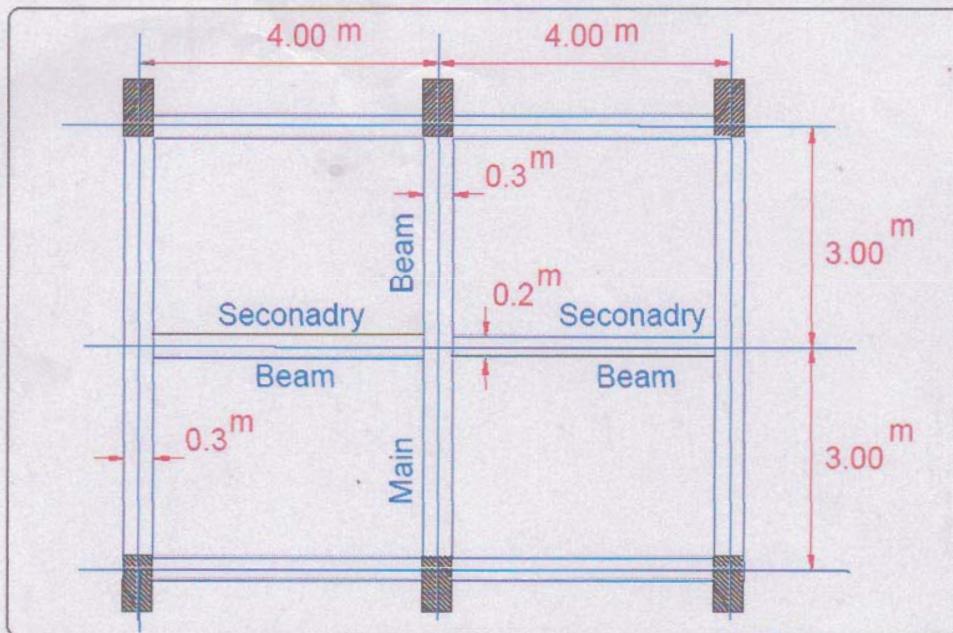

Functionality of Beams:

- 1- Placing under the walls to avoid excessive deflections .
- 2- Placing over the walls for supporting and linteling.
- 3- Divided the reinforced concrete slabs of large area to be in a suitable thickness.
- 4- Connect the columns together to get best moment distribution.
- 5- Reduce the buckling length of columns.

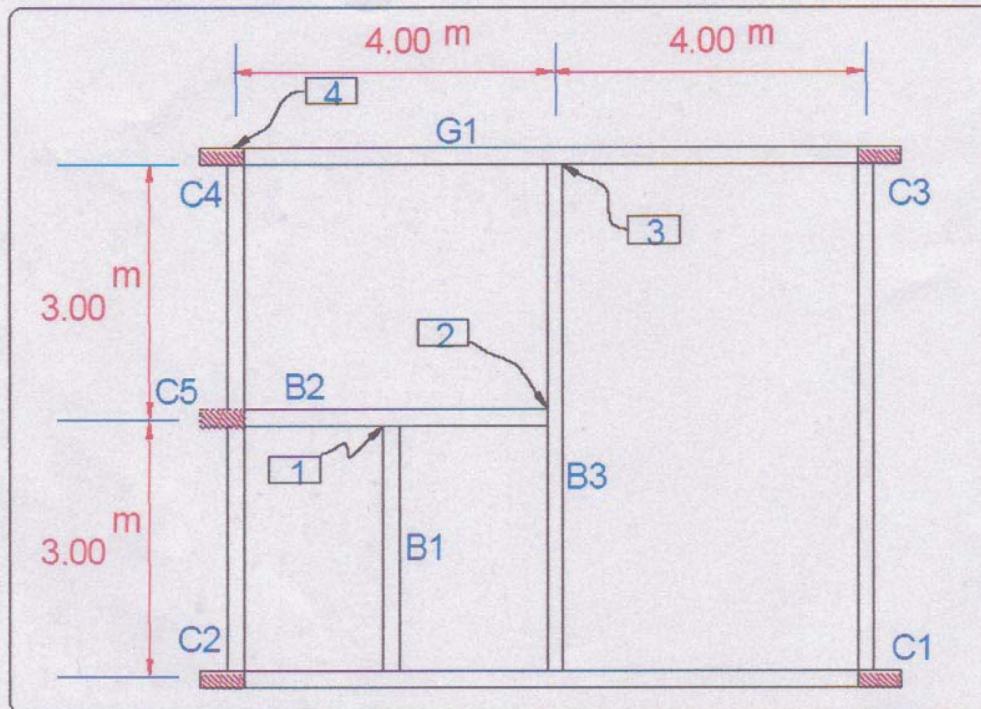

Types of Beams:

- 1- Main girders.(load carrier)
- 2- Secondary beams.(load transferor)

Beams distribution:

- 1- The following figure showed a wrong distribution of secondary beams, because there are three secondary beams loaded on each other (B1 & B2 & B3), then the load transmit to the main beam.

2- Circumference columns (Corners and edges) must be connected to each other by beams.

3- Avoid the loop of loading, or interior cantilever in beams distribution.
