*Analytical Chemistry*  
*Lecture 1*  
*Concentration*

## Concentration

The amount of solute dissolved in a certain amount of solution is called the **concentration** of the solution. Although there are many ways to express a concentration, they all specify a certain amount of solution.

$$\text{Concentration of a solution} = \frac{\text{amount of solute}}{\text{amount of solution}}$$

## Mass Percent

The mass percent ( %m / m ) concentration of a solution is the percent by mass of solute in a certain mass of solution. This is also known as weight percent ( %wt / wt ). In laboratory, both solute and solution are weighed on a balance.

$$\text{mass \%} = \frac{\text{mass of solute ( g )}}{\text{mass of solution ( g )}} \times 100\%$$

## Mass Percent

The mass percent ( %m / m ) concentration of a solution is the percent by mass of solute in a certain mass of solution. This is also known as weight percent ( %wt / wt ). In laboratory, both solute and solution are weighed on a balance.

$$\text{mass \%} = \frac{\text{mass of solute ( g )}}{\text{mass of solution ( g )}} \times 100\%$$

Suppose we prepared a solution by mixing 8.0 g of KCl (solute) with 42.0 g of water (solvent). Together the mass of the solute and mass of solvent give the mass of the solution (8.0 g + 42.0 g = 50.0 g) the mass % is calculated by substituting in the values into the mass percent expression.

$$\frac{8.0 \text{ g of KCl}}{50.0 \text{ g of solution}} \times 100\% = 16\% \text{ ( m / m )}$$

### Problem

What is the mass percent of a solution prepared by dissolving 30 g NaOH in 120 g of water ?

### Solution

30 g NaOH + 120 g water = 150 g of solution

$$\text{Mass\%} = \frac{30 \text{ g NaOH}}{150 \text{ g}} \times 100 \% = 20 \% \text{ ( m / m )}$$

### Volume Percent

Because the volume of liquids or gases can be easily measured, the concentrations of their solutions are often expressed as volume percent ( % v / v ). The units of volume used in the ratio must be the same, for example, both in milliliters or both in liters .

$$\text{Volume \%} = \frac{\text{Volume (mL) solute}}{\text{Volume (mL) solution}} \times 100 \%$$

We interpret a volume / volume percent as the volume of solute in 100 ml of solution. In the vinegar industry, a label that reads 12% (v/v) means 12 ml of alcohol in 100 ml in vinegar .

### Mass / volume percent

A mass / volume percent ( %m / v ), or weigh / volume percent, is calculated by dividing the grams of the solute by the volume of the ( ml ) of solution and multiplying by 100. Widely used in hospitals and pharmacies, the preparations of intravenous solutions and medicines involves the mass / volume percent .

$$\text{mass / volume \%} = \frac{\text{grams of solute}}{\text{milliliters of solution}} \times 100 \%$$

**Problem**

What is the mass / volume percent, % ( m / v ) of bromine in a solution prepared by dissolving 12 g of bromine in enough carbon tetra chloride to make 250 ml of solution ?

**Solution**

$$\text{mass / volume \%} = \frac{12 \text{ g Br}_2}{250 \text{ ml solution}} \times 100 \% = 2 \% ( \text{ m / v } ) \text{ Br}_2$$

**Molarity**

When the solutes of solutions take part in reactions, chemists are interested in the number of reacting particles. For this purpose use **Molarity ( M )**, a concentration that states the number of moles of solute in exactly 1 liter of solution. The molarity of a solution can be calculated knowing the moles of solute and the volume of solution.

$$\text{Molarity ( M )} = \frac{\text{moles of solute}}{\text{liters of solution}} = \frac{\text{Wt of solute}}{\text{M.Wt of solute}} \div \frac{\text{Liters of solution}}{\text{Liters of solution}}$$

For example, if 1.0 mole of NaCl were dissolved in enough water to prepare 1.0 L of solution, the resulting NaCl solution has a molarity of 1.0 M. the abbreviation M indicates the units of moles per liter ( moles / L ).

$$\begin{aligned} \text{Molarity ( M )} &= \frac{\text{moles of solute}}{\text{liters of solution}} = \frac{1.0 \text{ mole NaCl}}{1.0 \text{ L of solution}} = \frac{1.0 \text{ mole NaCl}}{1.0 \text{ L of solution}} \\ &= \mathbf{1.0 \text{ M NaCl}} \end{aligned}$$

Problem

What is the molarity of 60 g of NaOH in 0.25 L solution ?

Solution

Because molarity requires moles of solute, we convert grams of NaOH to moles of NaOH using the molar mass NaOH ( 40 ).

$$\begin{array}{l}
 \text{60 g NaOH} \times \frac{1 \text{ mole NaOH}}{40 \text{ g NaOH}} = 1.5 \text{ moles NaOH} \\
 \text{Grams of NaOH} \qquad \qquad \qquad \text{Molar mass} \\
 \\
 \text{Moles of solute} \\
 M = \frac{1.5 \text{ moles NaOH}}{0.25 \text{ L}} = 6 \text{ M} \\
 \text{liters of solution}
 \end{array}$$

Normality

The number of gram equivalent wt which dissolve in 1 L of solvent

$$\text{Normality} = \frac{Wt}{Eq. wt} \times \frac{1000}{V}$$

$$\begin{array}{l}
 Wt = \text{weigh} \\
 Eq. Wt = \text{equivalent weigh} \\
 V = \text{volume}
 \end{array}$$

$$\text{Eq. wt for acids} = \frac{M.Wt}{\text{No of H}^+}$$

HCL , H<sub>2</sub>SO<sub>4</sub> , H<sub>3</sub>PO<sub>4</sub>

$$\text{Eq. wt for Basie} = \frac{M.Wt}{\text{No of HO}^-}$$

NaOH , Ca(OH)<sub>2</sub> , Al(OH)<sub>3</sub>

$$\text{Eq. wt for salts} = \frac{M.Wt}{\text{No of atoms} \times \text{metal equivalent}}$$

( NaCl , Na<sub>2</sub>SO<sub>4</sub> , Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> )

$$\text{Eq. wt for oxi-red} = \frac{M.Wt}{\text{No of electron donor or excepted}}$$

= 5 e-

For liquid

$$N = \frac{\text{Specific gravity} \times \text{percentage or density} \times 1000}{\text{equivalent weight}}$$

$$M = \frac{\text{Specific gravity} \times \text{percentage or density} \times 1000}{\text{molecular weight}}$$

### Problem

Prepare 0.1 N of HCl in 250 ml if you know the Specific gravity is equal 1,1 and the acid percentage 30-34 %

### Solution

$$N = \frac{1.1 \times \frac{32}{100} \times 1000}{36.5} = 10 \text{ N}$$

$$N_1 \times V_1 = N_2 \times V_2$$

$$10 \times V_1 = 0.1 \times 250 \text{ ml}$$

$$V_1 = 0.25 \text{ ml}$$
