## Theory of Turbo machines

In turbo machine theory:
1- Friction is neglected
2- The fluid is assumed to have perfect guidance through the machine, i.e., an infinite number of thin vanes.

## Water Turbines

## 1- Impulse Turbine

All the available energy of the flow is converted by a nozzle into kinetic energy at atmospheric pressure before the fluid contacts the moving blades. It is suitable for high heads.

The most common type of these turbines is Pelton Wheel which is composed of:
1-One or more stationary inlet nozzle(s).
2-Runner attached to it a number of buckets
3- Casing

$$
V_{l}=U+V_{r}
$$

Velocity Diagram at Exit

$V_{1}=U+V_{r}$

V : Liquid absolute velocity
U : blade speed
Vr: Liquid relative velocity $\alpha$ : Bucket angle

Notes:
1- Ignoring the friction between the liquid and the blades and since the inlet and exit ports are in at atmospheric pressure, hence Vr is the same at inlet and exit.
2- The absolute velocity of liquid at exit $\mathrm{V}_{2}$ represents waste energy.
In order to calculate the inlet absolute velocity (jet velocity), apply Bernoulli equation:
$\mathrm{Pa}+0+1 / 2 \rho \mathrm{gh}=\mathrm{Pa}+1 / 2 \rho \mathrm{~V}_{1}{ }^{2}$
$V_{1}=\sqrt{2 g h}$
And taking into account the nozzle opening loss, then:
$V_{1}=C v \sqrt{2 g h}$
Where Cv is the nozzle coefficient.

## Momentum balance

$\Sigma \mathrm{F}=\mathrm{M}_{\text {out }}-\mathrm{M}_{\text {in }}$
$\mathrm{F}=-\rho \mathrm{Q} \mathrm{V}_{\mathrm{r}} \operatorname{Cos} \alpha-\rho \mathrm{Q} \mathrm{V}_{\mathrm{r}}$ (of liquid)
$F=-\rho Q\left(V_{1}-U\right)(1+\operatorname{Cos} \alpha)($ of liquid $)$
$\mathrm{F}=\rho \mathrm{Q}\left(\mathrm{V}_{1}-\mathrm{U}\right)(1+\operatorname{Cos} \alpha)($ on blades $)$

Power of Turbine $\left(\mathrm{W}_{\mathrm{T}}\right)$
$\mathrm{W}_{\mathrm{T}}=\omega \mathrm{T}$
$\omega=\mathrm{U} / \mathrm{r}$
$T=F X r$

Hence:

$$
W_{T}=\rho Q U\left(V_{1}-U\right)(1+\operatorname{Cos} \alpha)
$$

$Q$ is the total flow rate of water
$Q=A V_{1}$
$A$ is the area of the nozzle
$A=\pi / 4\left(d j^{2}\right)$
$d j$ is the nozzle diameter

## Speed Factor

$$
\phi=\frac{U}{\sqrt{2 g h}}
$$

From the output power equation above, it could be concluded at first sight that the maximum power is attained when the value of $\alpha$ equals to zero. But this is not attainable practically as the exiting liquid must stay free of the tailing buckets. To obtain the condition of the maximum power we derive the power relation with respect to U :
$\mathrm{d} W_{T} / d U=\rho Q\left(V_{l}-2 U\right)(1+\operatorname{Cos} \alpha)=0$
hence $\mathrm{U}=\mathrm{V}_{1} / 2$ or $(\Phi=\mathrm{Cv} / 2)$ is the condition of the maximum power
$W_{T \max }=\rho Q U^{2}(1+\operatorname{Cos} \alpha)$

## Turbine Efficiency

$\zeta_{T}=\frac{W_{T}}{\gamma Q h}$
$\zeta_{T}=\frac{\rho Q U\left(V_{1}-U\right)(1+\cos \alpha)}{\rho g Q h}$
$\zeta_{\mathrm{T}}=2 \Phi(\mathrm{Cv}-\Phi)(1+\cos \alpha)$

## Example

A Pelton wheel is supplied with $0.035 \mathrm{~m}^{3} / \mathrm{s}$ of water under a head of 92 m . The wheel rotates at 725 rpm and the velocity coefficient of the nozzle is 0.95 . The efficiency of the wheel is $82 \%$ and the speed factor is 0.45 . Determine the following:

1. Speed of the wheel
2. Wheel to jet diameter ratio
3. The developed power
4. The bucket angle

## Solution

$\mathrm{U}=\omega$ r Or $\phi=\frac{U}{\sqrt{2 g h}}$ hence, $\mathrm{U}=0.45 \times(2 \times 9.81 \times 92)^{1 / 2}=19.12 \mathrm{~m} / \mathrm{s}$
Wheel diameter D
$\omega=\mathrm{U} / \mathrm{r} \quad$ Or $\mathrm{r}=\mathrm{U} / \omega \quad$ hence, $\mathrm{r}=19.12 /(2 \pi \times 725 / 60)=0.252 \mathrm{~m}$
Hence $D=2 r=0.504 \mathrm{~m}$

## Jet diameter d

$\mathrm{Q}=\mathrm{A}_{1} \mathrm{~V}_{1}=\pi / 4 \mathrm{~d}^{2} \times \mathrm{V}_{1}$
$\mathrm{V} 1=\mathrm{Cv}(2 \mathrm{gh})^{1 / 2}=0.95(2 \times 9.81 \times 92)^{1 / 2}=40.36 \mathrm{~m} / \mathrm{s}$
$0.035=\pi / 4 \mathrm{~d}^{2} \mathrm{x} 40.36 \rightarrow \mathrm{~d}=0.033 \mathrm{~m}$
Hence the ratio $\mathrm{D} / \mathrm{d}=0.504 / 0.033=15.12$
$\zeta_{T}=\frac{W_{T}}{\gamma Q h}$
Hence WT=0.82 $\times 9810 \times 0.035 \times 92=25902$ Watts
$\zeta_{\mathrm{T}}=2 \Phi(\mathrm{Cv}-\Phi)(1+\cos \alpha)$
$0.82=0.9(0.95-0.45)(1+\cos \alpha)$
$\cos \alpha=0.822$
Hence $\alpha=34.7^{\circ}$

## Reaction Turbine

In the reaction turbine a portion of the energy of the fluid is converted into kinetic energy by the fluid's passing through fixed vanes before entering the runner, and the remainder of conversion takes place through the runner.

1- Francis Turbine
$\checkmark$ The function of the guide vane is to control the tangential component of velocity at the runner inlet.
$\checkmark$ The function of the draft tube is to convert the kinetic energy remaining in the liquid into flow energy.
$\checkmark$ The pressure at the runner exit is below atmospheric.

$\alpha_{1}$ : guide vane angle
$\beta_{1}$ : blade angle at inlet
$\alpha_{2}$ : Exit fluid angle
$\beta_{2}$ : blade angle at exit
$\mathrm{V}_{1}$ : absolute velocity at inlet
$\mathrm{V}_{2}$ : absolute velocity at exit
$\mathrm{V}_{\mathrm{r} 1}$ : relative velocity at inlet
$\mathrm{V}_{\mathrm{r} 2}$ : relative velocity at exit
$\mathrm{U}_{1}$ : Blade or runner speed at inlet
$\mathrm{U}_{2}$ : Blade or runner speed at exit
$\mathrm{V}_{\mathrm{n} 1}=\mathrm{V}_{1} \sin \alpha_{1}$ : normal component of $\mathrm{V}_{1}$
$V_{n 2}=V_{2} \sin \alpha_{2}$ : normal component of $V_{2}$
$\mathrm{V}_{\mathrm{w} 1}=\mathrm{V}_{1} \cos \alpha_{1}$ : tangential component of $\mathrm{V}_{1}$
$\mathrm{V}_{\mathrm{w} 2}=\mathrm{V}_{2} \cos \alpha_{2}$ : tangential component of $\mathrm{V}_{2}$

## Momentum Balance

$\mathrm{T}=\rho \mathrm{Q}\left(\mathrm{V}_{\mathrm{w} 1} \times \mathrm{r}_{1}-\mathrm{V}_{\mathrm{w} 2} \times \mathrm{r}_{2}\right)$
$\mathrm{W}_{\mathrm{T}}=\omega \mathrm{T}$
$W_{T}=U / r \rho Q\left(V_{w 1} \times r_{1}-V_{w 2} \times r_{2}\right)$

$$
\mathrm{W}_{\mathrm{T}}=\rho \mathrm{Q}\left(\mathrm{~V}_{\mathrm{w} 1} \mathrm{U}_{1}-\mathrm{V}_{\mathrm{w} 2} \mathrm{U}_{2}\right)
$$

$$
\zeta_{T}=\frac{W_{T}}{\gamma Q h}
$$

$$
\mathrm{Q}=\mathrm{A} \mathrm{Vn}=2 \pi \times \mathrm{r}_{1} \times \mathrm{b}_{1} \times \mathrm{V}_{\mathrm{n} 1}=2 \pi \times \mathrm{r}_{2} \times \mathrm{b}_{2} \times \mathrm{V}_{\mathrm{n} 2}
$$

Guide Vane Angle Relation
Referring to the inlet velocity diagram:
$\mathrm{V}_{\mathrm{w} 1}=\mathrm{U}_{1}+\mathrm{V}_{\mathrm{n} 1} / \tan \beta_{1}$
$\tan \alpha_{1}=\mathrm{V}_{\mathrm{n} 1 /} \mathrm{V}_{\mathrm{w} 1}$
and from flow rate relation $\mathrm{V}_{\mathrm{n} 1}=\mathrm{Q} /\left(2 \pi \mathrm{r}_{1} \mathrm{~b}_{1}\right)$

Hence,
$\cot \alpha_{1} \mathrm{Q} /\left(2 \pi \mathrm{r}_{1} \mathrm{~b}_{1}\right)=\omega \mathrm{r}_{1}+\cot \beta_{1} \mathrm{Q} /\left(2 \pi \mathrm{r}_{1} \mathrm{~b}_{1}\right)$
$\cot \alpha_{1}=\frac{2 \pi r_{l} b_{1}}{Q} \omega+\cot \beta_{l}$
$\alpha_{1}=\cot ^{-1}\left[\frac{2 \pi r_{1} b_{1}}{Q} \omega+\cot \beta_{1}\right]$

This relation discover the importance of controlling the angular speed by varying the guide vane angle to components any changes in the flow rate.

## Notes:

1- Radial Discharge: $\alpha_{2}=90^{\circ} \rightarrow \mathrm{V}_{\mathrm{w} 2}=0 \rightarrow \mathrm{~W}_{\mathrm{T}}=\rho \mathrm{QV}_{\mathrm{w} 1} \mathrm{U}_{1}$
2- Radial inlet blades: $\beta_{1}=90^{\circ} \rightarrow \mathrm{V}_{\mathrm{w} 1}=\mathrm{U}_{1}$
Example: A Francis turbine has radii of $r_{1}=0.2 \mathrm{~m}$ and $\mathrm{r}_{2}=0.1 \mathrm{~m}$, operates under the following conditions: $\mathrm{Q}=0.06 \mathrm{~m}^{3} / \mathrm{s}$, rotational speed $=240 \mathrm{rpm}$, guide vane angle $=30^{\circ} \alpha_{2}=80^{\circ}$, absolute velocity at inlet and outlet, respectively, $6 \mathrm{~m} / \mathrm{s}$ and $3 \mathrm{~m} / \mathrm{s}$. Take the turbine efficiency as $90 \%$. Find (1) the developed power (2) the applied head (3) inlet blade angle and (3) the thickness of the inlet impeller.

Solution:
$\mathrm{V}_{\mathrm{w} 1}=\mathrm{V}_{1} \cos \alpha_{1}=6 \cos 30=5.2 \mathrm{~m} / \mathrm{s}$
$\mathrm{V}_{\mathrm{w} 2}=\mathrm{V}_{2} \cos \alpha_{2}=3 \cos 80=0.521 \mathrm{~m} / \mathrm{s}$
$\mathrm{U}_{1}=\omega \mathrm{r}_{1}=2 \pi \times 240 / 60 * 0.2=5.03 \mathrm{~m} / \mathrm{s}$
$\mathrm{U}_{2}=\omega \mathrm{r}_{2}=2 \pi \times 240 / 60 * 0.1=2.51 \mathrm{~m} / \mathrm{s}$
$\mathrm{W}_{\mathrm{T}}=1000 \times 0.06(5.2 \times 5.03-0.521 \times 2.51)=\underline{1490.9 \mathrm{Watts}}$
$\zeta_{T}=\frac{W_{T}}{\gamma Q h}$
$\mathrm{~h}=1490.9 /(0.9 \times 9810 \times 0.06)=\underline{2.814 \mathrm{~m}}$
$\tan \beta_{1}=\mathrm{V}_{\mathrm{n} 1} /\left(\mathrm{V}_{\mathrm{w} 1}-\mathrm{U}_{1}\right)$
$\tan \alpha_{1}=\mathrm{V}_{\mathrm{n} 1} / \mathrm{V}_{\mathrm{w} 1}$
$\mathrm{~V}_{\mathrm{n} 1}=\tan ^{30} \times 5.2=3 \mathrm{~m} / \mathrm{s}$
$\beta_{1}=\tan ^{-1}(3 /(5.2-5.03))=\underline{86.7}$
$\mathrm{Q}=2 \pi \mathrm{r}_{1} \mathrm{~b}_{1} \mathrm{~V}_{\mathrm{n} 1}$
Hence,
$\mathrm{b}_{1}=0.06(2 \pi \times 0.2 \times 3)=\underline{0.016 \mathrm{~m}}$

## 2-Kaplan Turbine

The Kaplan turbine, named after Victor Kaplan, a German professor, is an efficient axial-flow hydraulic turbine with adjustable blades. It is the most efficient type at very low heads.
-To satisfy large power demands, very large volume flow rates necessary in the Kaplan turbine i.e. the product Qh is large.
-The flow enters from a volute into the inlet guide vanes which impart a degree of swirl to the flow.
-The overall flow configuration is from radial to axial
-The number of blades is small, usually 4,5 or 6
-The blades are designed with a twist suitable for free-vortex flow at entry and axial flow at outlet.
-The Kaplan turbine incorporates one essential feature not found in other turbines that is setting of the blades angle can be controlled.

$$
\mathrm{Q}=2 \pi \mathrm{r}_{\mathrm{i}} \times \mathrm{t} \times \mathrm{V}_{\mathrm{i}}=\pi / 4 \times\left(\mathrm{D}_{\mathrm{t}}^{2}-\mathrm{D}_{\mathrm{h}}^{2}\right) \mathrm{V}_{\mathrm{a}}
$$

$$
\mathrm{W}_{\mathrm{T}}=\rho \mathrm{QUV}_{\mathrm{w} 1}
$$

Turbine efficiency

$$
\zeta_{T}=\frac{W_{T}}{\gamma Q h}=\frac{\rho Q U V w_{1}}{\rho g Q h}=\frac{U V w_{1}}{g h}
$$

## Free Vortex Principle

$$
\mathrm{V}_{\mathrm{w}} \mathrm{Xr}=\mathrm{constant}
$$

Example: A Kaplan turbine develops 9 MW and rotates at 145 rpm under a head of 20 m . The tip and hub diameters are 4 m and 1.75 m respectively. Calculate the inlet and outlet blade angle measured at mean radius if turbine efficiency is $90 \%$.
$\mathrm{D}_{\mathrm{m}}=(4+1.75) / 2=2.875 \mathrm{~m}$
$\mathrm{U}=\omega \mathrm{r}_{\mathrm{m}}=(2 \pi \mathrm{~N} / 60) \times 2.875 / 2=21.83 \mathrm{~m} / \mathrm{s}$
$\tan ^{-1}(90-\beta)=\mathrm{Va} /\left(\mathrm{U}-\mathrm{V}_{\mathrm{w} 1}\right)$
$\zeta_{T}=\frac{U V w_{1}}{g h}$
$\rightarrow \mathrm{V}_{\mathrm{wl}}=0.9 \times 9.81 \times 20 / 21.83=8.088 \mathrm{~m} / \mathrm{s}$
$\mathrm{Q}=\pi / 4 \times\left(\mathrm{D}_{\mathrm{t}}^{2}-\mathrm{D}_{\mathrm{h}}{ }^{2}\right) \mathrm{V}_{\mathrm{a}}$
$\mathrm{W}_{\mathrm{T}}=\rho \mathrm{QUV}_{\mathrm{w} 1}$
$\mathrm{Q}=9 \times 103 / 1000 \times 8.088 \times 21.83=50.97$
$50.97=\pi / 4 \times\left(4^{2}-1.75^{2}\right) V_{a}$
$\rightarrow \mathrm{Va}=5.02 \mathrm{~m} / \mathrm{s}$
$90-\beta_{1}=5.02 /(21.83-8.088)=20^{\circ}$
$\beta 1=70^{\circ}$
$\beta 2=\tan ^{-1} \mathrm{U} / \mathrm{Va}=21.33 / 5.02=77^{\circ}$

## Homologous Machines

## Assumptions

1- The machines are geometrically similar $\left(\beta_{\mathrm{i} 1}=\beta_{\mathrm{i} 2}\right)$
2- Similar stream lines i.e. the Reynolds number is the same in the similar machines
This results in a similar velocity triangle in the inlet.
$\mathrm{V}_{1} / \mathrm{U}_{1}=\mathrm{V}_{2} / \mathrm{U}_{2}$
Or V/U=const.
$\mathrm{U}=\omega \mathrm{r}$
$\omega \alpha \mathrm{N}$
$r \alpha D$
UaND
VaUaND
$\mathrm{Q}=\mathrm{AVn}$,
$\mathrm{A} \alpha \mathrm{D}^{2}$
VnoV
Q $\alpha \mathrm{ND}^{3}$

$$
\begin{equation*}
\frac{Q}{N D^{3}}=\text { const } \tag{1}
\end{equation*}
$$

$\mathrm{Q}=\mathrm{CdA}(2 \mathrm{gh})^{1 / 2}$
$\mathrm{Q} \alpha \mathrm{D}^{2} \mathrm{H}^{1 / 2}$
$\mathrm{ND}^{3} \alpha \mathrm{D}^{2} \mathrm{H}^{1 / 2}$
$\mathrm{ND} \alpha \mathrm{H}^{1 / 2}$

$$
\begin{equation*}
\frac{H}{N^{2} D_{2}}=\text { const } . \tag{2}
\end{equation*}
$$

$\mathrm{Wt}=\gamma \mathrm{Qh}$
Wt $\alpha \mathrm{ND}^{3} \mathrm{~N}^{2} \mathrm{D}^{2}$

$$
\begin{equation*}
\frac{W_{T}}{N^{3} D^{5}}=\text { const. } \tag{3}
\end{equation*}
$$

Relations 1 to 3 are called the turbo-machinery Similarity rules, are used to:
1-Design or select a turbo machine from a family of geometrically similar units
2- Examine the effects of changing speed, fluid or size on a given unit. 3- To design a pump to deliver flow on the moon or on a space station!

## Specific speed

1) Specific Speed for Turbines
$\frac{Q}{N D^{3}}=$ const.
$\left[\frac{H}{N^{2} D_{2}}=\right.$ const.
$\ldots . . . .(2)]^{3 / 2} \rightarrow \mathrm{H}^{3 / 2} / \mathrm{N}^{3} \mathrm{D}^{3}=$ cons.
$\mathrm{H}^{3 / 2} / \mathrm{N}^{2} \mathrm{Q}=$ const.
$\mathrm{H}^{3 / 2} \mathrm{H} / \mathrm{N}^{2} \mathrm{~W}_{\mathrm{T}}=$ const.
$\left[\mathrm{H}^{5 / 2} / \mathrm{N}^{2} \mathrm{~W}_{\mathrm{T}}=\text { const. }\right]^{1 / 2}$

$$
\frac{N \sqrt{\mathbf{W}_{\mathbf{T}}}}{\mathbf{H}^{5 / 4}}=\text { cons. }=N s
$$

Where:
N : in rpm
WT: in kW
H : in m
2) Specific Speed for Pumps

$$
\begin{aligned}
& {\left[\frac{H}{N^{2} D_{2}}=\text { const. } \quad \ldots \ldots .(2)\right]^{3 / 2} \rightarrow \mathrm{H}^{3 / 2} / \mathrm{N}^{3} \mathrm{D}^{3}=\text { cons. }} \\
& {\left[\mathrm{H}^{3 / 2} / \mathrm{N}^{2} \mathrm{Q}=\text { const }\right]^{1 / 2} \rightarrow \mathrm{H}^{3 / 4} / \mathrm{NQ}^{1 / 2}=\text { const }}
\end{aligned}
$$

$$
\frac{N \sqrt{\mathbf{Q}}}{\mathbf{H}^{3 / 4}}=\text { cons. }=N s
$$

Where:
N : in rpm
Q: in m3/s
H : in m

## Example:

Two similar pumps A and B, the angular speed of pump A is 1000 rpm and the head developed is 12.2 m of water with a flow rate of 0.0151 $\mathrm{m}^{3} / \mathrm{s}$. Pump B is has a diameter twice that of Pump A. Find the angular speed and the head developed by pump B when its flow rate is 0.0453 $\mathrm{m}^{3} / \mathrm{s}$. What is the specific speed of this type of pump?
$\mathrm{Q}_{1} / \mathrm{N}_{1} \mathrm{D}^{3}{ }_{1}=\mathrm{Q}_{2} / \mathrm{N}_{2} \mathrm{D}^{3}{ }_{2} \rightarrow 0.0151 / 1000 \times \mathrm{D}^{3}{ }_{1}=0.0453 / \mathrm{N}_{2}\left(2 \mathrm{D}_{1}\right)^{3}$ $\mathrm{N}_{2}=375 \mathrm{rpm}$
$\mathrm{H}_{1} /\left(\mathrm{N}^{2}{ }_{1} \mathrm{D}^{2}{ }_{1}\right)=\mathrm{H}_{2} /\left(\mathrm{N}_{2}{ }_{2} \mathrm{D}_{2}{ }^{2}\right) \rightarrow 12.2 /(1000)^{2} \mathrm{D}_{1}{ }^{2}=\mathrm{H}^{2} /(375)^{2}\left(2 \mathrm{D}_{1}\right)^{2}$ $\mathrm{H}_{2}=6.86 \mathrm{~m}$

$$
N s=\frac{N \sqrt{\mathbf{Q}}}{\mathbf{H}^{3 / 4}} \rightarrow N s=\frac{1000 \sqrt{\mathbf{0 . 0 1 5 1}}}{\mathbf{1 2 . 2 ^ { 3 / 4 }}}=18.82
$$
